1 INTRODUCTION

7 Hello, how are we doing?

2 METHODS

2.1 Generating Predictions

9 Used GOMAP on condo lalala. Input files are (usually) published along results.

2.2 Clean up

11 All functional annotation sets were cleaned up the following way (using definitions from the Gene
12 Ontology version 2019-07-01):

13 1. Any annotations where the GO accession was marked as obsolete were removed.
14 2. Some terms in the GO have 'alternative ids'. When naively removing duplicates, two entries will not
15 be recognized as duplicates if they have different accessions pointing to the same GO term. Therefore,
16 all GO accessions were changed to their respecitve 'main id' and the dataset was again scanned for
17 duplicates.
18 3. Any annotations with modifiers (NOT, contributes_to...) were removed since no tool used in the
19 further analysis can handle them.

20   Table 1 provides information on the number of annotations that were removed this way from each dataset.
21   All further analyses were performed on the cleaned datasets since we assume the user will only be interested
22   in still valid and non-redundant functional annotations.

2.3   Quantitative Evaluation

24   lalala lololo table xyz

2.4   Quality Evaluation

26   Quality evaluation of gene function predictions is not trivial and usually done by comparing the set of
27   predicted functions of a gene against a *gold standard* consisting of annotations that are assumed to be
28   correct. We used annotations that were created or in some way curated with human participation for gold
29   standards. There are a plethora of different metrics to perform the comparison of predictions against this
30   gold standard. When we first published GOMAP (Wimalanathan et al., 2018), we used a modified version
31   of the hierarchical evaluation metrics originally introduced in (Verspoor et al., 2006) because they were
32   simple, clear, and part of an earlier attempt at unifying and standardizing GO annotation comparisons
33   (Defoin-Platel et al., 2011). In the meantime, Plyusnin et al. (2019) have published an approach for
34   evaluating different metrics showing substantial differences within the robustness of different approaches.
35   `TODO DESCRIBE THEIR APPROACH` We have applied their method on the Gold Standards available
36   to us to determine which evaluation metric is the most appropriate in our case. The results of this analysis
37   can be seen in `TODO`.

38   We then evaluated our predictions and the other annotation sets using the best performing metrics as well
39   as the one we previously used (Table `TODO`).

2.5   Phylogenetic Tree Construction

41   To demonstrate that a more top-level and holistic use of whole-genome functional predictions can still be
42   useful we devised some simple ways of applying phylogenetic methods to our predictions. ### Distance
43   Based ### Character Based

2.6   Ensuring Reproducibility

45   containerization, github...

3   RESULTS

46   ... a quantitative comparison of the datasets in Table.

3.1   Quality Evaluation

48   `TODO` If it turns out that our predictions are good with hF but bad with more approriate metrics,
49   explanation would be that score thresholds for the prediction tools used in the GOMAP pipeline have
50   been chosen to maximize this hF value. It now seems reasonable to re-adjust these thresholds to maximize
51   a different metric which will likely result in a drop in hF score but increase in other metrics. Again
52   emphasizes the importance of choosing the right evaluation metric. Also shows how comparison between
53   different pipelines/predictions can be difficult if chose different metric or optimized for different metric.
54   Also: if an annotation is not present in the gold standard, there is no way of knowing whether that gene
55   truly doesn't have that function or whether it has just never been characterized/examined. So we cannot
56   distinguish between a biologically true negative and an actually false negative in the gold standard. This

Table 1. Number of removed annotations during cleanup.

Genome	Dataset	Obsolete Annotations	Duplicates	Annotations with Modifiers
Arachis hypogaea	GOMAP	0	0	912

poses a problem when annotations are predicted that are not found in the gold standard: Is this truly a wrong prediction or is the gold standard incomplete? Especially in our case where the predictions not only contain more annotations than the gold standard, but are also more diverse. In effect this means that a quality score as calculated above may not only describe the quality of the prediction, but to some extent also the completeness of the gold standard itself. At least we can see here that gold standards with a median of 3 annotations per gene resulted in higher quality scores than gold standards with less annotations per gene, even though predictions were generated the same way in all cases. `TODO maybe put a figure with regression quality score/median annotations per gene or something` In conclusion this means that truly making a statement about the quality of a prediction set would require the ideal and complete gold standard. The scores we can generate so far are by far not as meaningful.

Download this table (CSV)

[a] How many genes in the genome have at least one GO term from the CC, BF, MP aspect annotated to them? A = How many at least one from any aspect? (A = CC ∪ BF ∪ MP)

[b] How many annotations in the CC, BF, and MP aspect does this dataset contain? A = How many in total? A = CC + BF + MP

[c] Take a typical gene that is present in the annotation set. How many annotations does it have in each aspect? A = How many in total? Please note that A ≠ CC + BF + MP

Table 3. Quality evaluation of the used GO annotation sets.
